

CHOICE OF PRICE INDEX FORMULAE

AT THE MICRO-AGGREGATION LEVEL:

THE CANADIAN EMPIRICAL EVIDENCE

Version updated in June 1995

The paper was initially presented at the first Meeting of the Ottawa Group on Price Indices, held in Ottawa, October 31 - November 2, 1994. This updated version includes price index series for some fresh produce and the results of quinquennial index linking, which were absent from the initial version. Also, Annex III is added with examples of series of actual price quotes. Finally, the updated version mentions that, from January 1995, geometric means started being used in the Canadian Consumer Price Index for the calculation of indices at the micro-aggregation level.

ABSTRACT

The problem of choosing a price index formula at the micro-aggregation level is discussed in the paper in the light of an empirical study that was carried out by the author in 1994. The study provides evidence that the choice of such formulae is of utmost importance to numerical results of indices. The proof is based on actual monthly price data for over 50 commodities, collected from December 1988 to January 1994 in the province of Ontario in the framework of the Consumer Price Index (CPI) survey. First, direct price indices were calculated on the preceding month time base, on the previous December time base, and on the December 1988 time base. They were derived from matched samples of prices using six formulae: ratios of equiweighted arithmetic, geometric and harmonic mean prices, as well as equiweighted arithmetic, geometric and harmonic means of price relatives. Next, chains of these indices were calculated on the December 1988 time base, alternatively with monthly, annual and quinquennial linking.

Differences in numerical results are stunning, in some cases they are tenfold and more. This means that the choice of micro-index formulae is a very important decision, likely more important than choosing a macro-index formula at higher aggregation levels. Another major conclusion from the study is that linking micro-indices, particularly frequent linking, greatly increases the effect of using alternative formulae. Consequently micro-index formulae should not be assessed solely according to their behaviour in direct price comparisons, but also, if not primarily, according to their comportment in chain price comparisons. Non-transitive formulae can play havoc with chain index numbers when relative prices tend to bounce.

Until 1994, micro-indices in the Canadian CPI have been calculated by monthly linking of the month-to-month ratios of arithmetic mean prices. As transitive formulae, the latter do not systematically bias the results, which was confirmed by the study. Nevertheless, a switch towards ratios of geometric mean prices was decided with the CPI basket update that took place in January 1995, to avoid problems with those categories of products that exhibit a broad spectrum of prices.

1.

BACKGROUND

Most national statistical agencies describe their consumer price index (CPI) as a measure of consumer price change obtained by comparing, over time, the cost of a certain basket of commodities. There is an abundant literature with long tradition on the basket-defined index formulae and their derivatives, crossed and chain formulae. Modern index numbers theory elaborated criteria for assessing these formulae according to their affinity with the cost-of-living indices based on certain forms of the utility function.

In practice, however, the concept of basket-defined indices is not used thoroughly across all stages of the CPI computation. Indeed, it is usually not applied at the very first stage, when "*micro-indices*" for specific commodities are directly derived from a collection of individual price quotes. Different countries use a variety of techniques to calculate micro-indices, sometimes based on quite arbitrary decisions, or even on obscure historical precedents.

Until recently, there was not much written on the topic of micro-index formulae, probably considered not challenging enough from intellectual point of view, and not sufficiently important for results of index numbers. In the current decade, though, its importance became recognised by statistical agencies and authors, for example Balk [1991], Dalén [1992], Moulton [1993], Reinsdorf [1993], Reinsdorf and Moulton [1994], Sellwood [1987], Turvey [1989].

In the Canadian practice, it was at the beginning of the eighties when Prices Division encountered some anomalies in the calculation of micro-indices. The anomalies were diagnosed as a result of linking arithmetic means of price relatives. This lead the author to a paper on chain price indices under the condition of "*bouncing*" relative prices [Szulc, 1983] and, later, to a more general paper explicitly addressing the problem of micro-index formulae [Szulc, 1987], where the use of geometric means was suggested. Both papers shared one weakness: absence of a realistic assessment of potential quantitative effects of using various micro-index formulae. Although the former paper contained numerical examples, the numbers were purposely made up to provide extreme results rather than taken from the CPI data. The only CPI index numbers available at that time for such comparisons were limited to a few commodities and to very short time intervals.

2.

OUTLINES OF THE EMPIRICAL STUDY

The purpose of the study, carried out in the Central Research Section of Prices Division, was to assess the long-term effect of using alternative micro-index formulae under conditions similar to those of the Canadian CPI production. Starting with the current CPI methodology and actual price data, different formulae and linking frequencies have been tested. The study became feasible thanks to a new CPI computerised system, which stores all collected price quotes and allows their retrieval for further processing.

In the Canadian CPI, micro-indices for designated commodities are calculated within spatial strata. The study used as primary inputs the price data for over 50 commodities, collected from December 1988 to January 1994 in the province of Ontario (taken as one spatial stratum). Prices collected less than once a month were carried over until the next price collection. Seasonal commodities were excluded. The number of monthly price figures used in the study ranged from 40 to 120 per commodity.

Six micro-index formulae have been taken into consideration in the study, of which three are ratios of mean prices collected in the base and observation times:

- a ratio of equiweighted arithmetic mean prices (**RAMP**),
- a ratio of equiweighted geometric mean prices (**RGMP**), and
- a ratio of equiweighted harmonic mean prices (**RHMP**).

Three other formulae are means of price relatives (expressing price change from the base to observation times for individual items):

- an equiweighted arithmetic mean of price relatives (**AMPR**),
- an equiweighted geometric mean of price relatives (**GMPR**), and
- an equiweighted harmonic mean of price relatives (**HMPR**).

The ratio of arithmetic mean prices was used in the Canadian CPI until 1994 as the main micro-index formula to estimate month-to-month price change for any given commodity within a given spatial stratum. To measure "*pure price change*", each ratio was calculated taking into account only prices from "**bilaterally matched samples**", i.e., only prices that have been collected during two consecutive months in the same outlet and that relate to the same item (unless adjusted for quality differences). Longer-term estimates of price change are obtained indirectly, through linking of these direct month-to-month micro-indices.

The study simulated the calculation of **direct month-to-month micro-indices derived from bilaterally matched samples** (using all six formulae) and their **monthly linking**. Matching was automatic in the case of means of price relatives, but required explicit exclusion of some collected price data when ratios of mean prices were used. The study also simulated the calculation of **direct micro-indices on the last December time base** and their **annual linking** (in December), an approach used by several countries. Finally, **direct micro-indices on the December 1988 time base** were calculated for the months from January 1989 to December 1993, and the direct indices for January 1994 on the December 1993 time base were linked to the latest of them in December 1993. This simulates a **quinquennial linking**, an approach used in the U.S.A by the Bureau of Labor Statistics.

With annual linking, bilateral matching of samples affects prices in all months of a given year and those in the last December, but not prices in all pairs of consecutive months, as in the case of monthly linking. With a single December 1993 linking, matching affects only prices in January 1994 and those in December 1988. For this reason, the results of monthly, annual and of quinquennial linking diverge not only because of a different frequency of linking, but also because of **differences in the effective price data base retained after the elimination of unmatched outlets and items**.

Annex I contains examples of tables 1a, 2a, and 3a with complete sets of chain index numbers obtained by linking various direct indices, from the time base of December 1988 until January 1994. These tables also include the corresponding sets of direct index numbers derived using the six micro-index formulae. Only series for a few selected commodities are presented, series for other commodities are available on request. Annex II shows the formulae that have been used for the calculation of the direct and chain price indices obtained from bilaterally matched samples.

To estimate the effect of changes in the linking frequency unhampered by differences in the matching procedure, yet another version of the study analysed micro-indices that, for every commodity, were derived from the same sample of outlets and items through all months from December 1989 to January 1994. This **common sample** excluded every outlet that have been absent from any monthly survey during the entire five year period, hence it is generally much smaller than the bilaterally matched samples for the same commodity. As with the bilaterally matched samples, all six micro-index formulae were used with the three types of linking. Tables 1b, 2b, and 3b of Annex I present the resulting direct and chain index numbers for the selected commodities. Formulae in Annex II relate to the indices obtained from common samples, as well.

3. NUMERICAL RESULTS OF THE STUDY

The following Summary Table A is an extract of the Tables 1a, 1b, and 1c for 24 commodities, which are shown in Annex I in their complete version for three commodities. It contains chain indices for January 1994 on the December 1988 time base. The five-year period 1989-1993 is sufficiently long to prove that the cumulative effect of using alternative micro-index formulae can be striking even under realistic conditions of the CPI production. In fact, differences between some index numbers are of the same order of magnitude as in the artificial examples made up by the author for his 1983 paper to shock the reader.

Summary Table A

There are relatively small differences between index numbers derived from micro-indices calculated as ratios of arithmetic, geometric and harmonic mean prices. No clear pattern appears with respect to the sign of these differences. For some commodities the highest index numbers were obtained with ratios of arithmetic mean prices (e.g., for potato chips, women's shoes), for some with harmonic means prices (e.g., for chicken, sofas), while index numbers obtained with ratios of geometric mean prices fell between these two. The uncertainty takes place even though the sign of differences between arithmetic, geometric and harmonic mean prices derived from the same sample is very predictable: an arithmetic mean price is never lower than the corresponding geometric mean price and the latter never lower than the corresponding harmonic mean price. However, because this relationship occurs at both the observation and base times, the differences between, say, a ratio of arithmetic mean prices and a ratio of harmonic mean prices can be positive or negative, depending on the case.

Differences between index numbers derived from micro-indices calculated as arithmetic, geometric and harmonic means of price relatives are much larger than the previously mentioned differences between micro-indices derived from ratios of arithmetic, geometric and harmonic mean prices. Signs of these differences are certain: an arithmetic mean of price relatives is never lower than their harmonic mean, while a geometric mean lies between the two. It can be seen that the amplitude of the differences grows with the frequency of linking and becomes astoundingly high in some cases of monthly linking. In the case of soft drinks, for example, the difference between the chain index numbers obtained by **monthly linking of arithmetic and harmonic means of price relatives cumulates to more than 900 index points over five years. It cumulates to more than 50 index points with annual linking and is still over ten index points with quinquennial linking.** The differences are even larger for some of the fresh produce.

A geometric mean of price relatives is always equal to the ratio of geometric mean prices derived from the same sample. It follows that the index numbers obtained using these two micro-index formulae are also always equal to each other. This is not the case with arithmetic or harmonic means. As anticipated by Szulc [1987], direct micro-index numbers derived using arithmetic (harmonic) means of price relatives tend to be higher (lower) than those obtained, respectively, from ratios of arithmetic (harmonic) mean prices. Linking, especially monthly linking, enhances these differences. Taking again soft drinks as example, the chain index number obtained through **monthly linking of arithmetic means of price relatives became almost eight times higher than the corresponding chain of ratios of arithmetic mean prices. It is more than 25% higher with annual linking, and still 5% higher with quinquennial linking.**

Linking of micro-indices affects the amplitude of all the discrepancies when non-transitive micro-index formulae are used for a set of commodities that exhibit "*bouncing relative prices*". This is shown in the Summary Table A, which ranks commodities by the amplitude of these differences. Many commodities that appear at the top of the Table, such as soft drinks, ground beef, chicken, or sugar, belong to typical "*loosing leaders*" on the Canadian retail market. To attract customers, they are frequently offered at very low prices, which then tend to rebound after a short period of time. For example, during the same three consecutive price surveys carried out in Toronto, a bottle of Coca Cola was sold in one outlet for \$0.49, \$0.99, and \$0.25, while in another one for \$0.99, \$0.49 and \$0.99, respectively. Annex III shows more examples of the kind.

Commodities at the bottom of the Summary Table A are much less subject to the *yo-yo* price behaviour. This explains why the use of various micro-index formulae only moderately affects their long-term index numbers. Lunches and hairdressing are good examples of these commodities.

The Summary Table A also exhibits some unexpected behaviour of index numbers obtained using transitive micro-index formulae. One would anticipate that transitive formulae, such as ratios of mean prices or geometric means of price relatives, will give the same index number whatever the frequency of linking (or with no linking at all). In the study, linking once a month

provided somewhat different index numbers than linking once a year. Taking as example ratios of arithmetic mean prices for soft drinks, the January 1994 index number of 115.0, obtained through monthly linking, is higher than the index number of 113.6 obtained through annual linking. The paradox is only spurious. The divergence is not caused by varying frequency of linking, but by the procedure of matching which creates different effective samples for month-to-month micro-indices (with monthly linking and monthly matching of samples), and for micro-indices on the last December time base (with annual linking and annual matching of samples).

When there is no change in the samples, index numbers are the same, as shown in the following Summary Table B, which is an extract of the Tables 2a, 2b, and 2c from Annex I. In contrast to Table A, all micro-indices used to produce Table B, whether their time base is the preceding month, the last December, or December 1988, were derived from a common sample of outlets and items for a given commodity. As a result, the January 1994 index numbers for soft drinks derived through monthly, annual or quinquennial linking of arithmetic mean prices are identical, at 115.0. The index numbers from Table B, however, may be somewhat less reliable than those from Table A, because common samples are generally smaller than those that are bilaterally matched for the same commodities.

Summary Table B

4. THE CHOICE OF MICRO-INDEX FORMULAE : MAIN ISSUES

This empirical study contributed to the debate on micro-indices in Prices Division, Statistics Canada. It is not that its findings are revolutionary, most of them have been brought up and discussed in the Division for almost two decades. Numerical evidence, however, has sometimes more convincing power than theoretical arguments.

The main conclusion is that the choice of micro-index formulae is a very serious business, with strong potential consequences on the resulting index numbers. In most practical cases, choosing a micro-index formula is likely to be more important than choosing a given basket-defined or another macro-index formula for higher aggregation levels. A comparison between the range of numerical results obtained in the present study and the range of results obtained by applying various macro-index formulae to the Canadian CPI (see Généreux [1983]) is quite indicative of that proposition.

The proposition seems to be particularly valid when short- and medium-term price changes are estimated (say, changes over a period of five years or less), whose knowledge is essential to many practical CPI applications, like monitoring inflation or finding escalators to compensate for the lost purchasing power of nominal incomes. Over these periods of time, the question whether the CPI should be, for example, of the Laspeyres or the Paasche form, is not vital. Indeed, it is only over longer periods of time, under the effect of changing macro-economic and macro-social conditions, that the population's spending patterns exhibit tangible changes, which warrant searching for a relevant basket-defined price index formula. Over short- and medium-term periods, manifold and often chaotic fluctuations on the retail market influence the CPI more than changes in the spending patterns, and they affect the CPI through its micro-indices.

Another major conclusion from the empirical study is that linking of micro-indices, particularly frequent linking, greatly increases the effect of using alternative formulae. This means that the micro-index formulae should not be assessed solely according to their behaviour in direct price comparisons, but also, if not primarily, according to their comportment in chain price comparisons. Therefore, the criteria of selecting micro-index formulae that are deduced, implicitly or explicitly, from direct price comparisons, should be used with caution, and never without considering the problem of transitivity. Concordance with the distribution of prices or price relatives might be quoted as one of those criteria, similarity to a specific form of indices of the basket-defined index family, as another one.

Since linking of micro-indices appears to be the main cause of their *misbehaviour*, the question might be asked why not to avoid linking as much as possible. In reality, the occurrence of micro-index linking cannot be eliminated altogether. Some replacements of outlets and priced items have to take place, and this means index linking, whether it is called by its name or not. Without the replacements, samples would soon become very thin, if kept matched, or, if no matching was performed, they would lose their capacity to estimate pure price change.

A less radical action would be to reduce the frequency of linking. The Canadian CPI practice of deriving direct month-to-month indices and of their subsequent monthly linking seems to be particularly inadequate in this respect. Yet, this practice has a big advantage: it enhances flexibility in the selection of items whose prices are collected and of outlets where the prices are collected, while maintaining the rule of matched samples. In this case, the bilateral matching affects only two consecutive monthly samples, whereas outlets and items can be updated for the next month-to-month price comparison, which enhances the relevancy of index numbers to the current market reality. This practice, however, makes the problem of transitivity of micro-indices even so more crucial.

Non-transitive formulae can play havoc with chain index numbers when relative prices tend to bounce, which is typical not only of the commodities with price seasonality, but also of those subject to short-term special pricing strategy. One could eliminate a lot of trouble if these special prices were ignored in price surveys. However, this is not a very valid recommendation. Price collectors would have to take many arbitrary decisions whether the displayed price reduction is temporary, and would not always get much help in this matter from shop managers, either because they do not want to answer the question or do not know the answer. In addition, when an item is actually sold at reduced prices, whether temporarily or not, this should be recognised as a price drop. There might even be some longer-term effect on the cost of living, if the frequency of special pricing varies through time, which may occur with business cycles or local competition wars.

If one accepts that the capacity of an ongoing substitution of surveyed outlets and items is a desirable feature of the CPI methodology, and if one rejects the idea of ignoring special prices, a transitive micro-index formula remains the only sensible choice. The formula used in the Canadian CPI until 1994, namely monthly linking of month-to-month ratios of arithmetic mean prices belongs to this category. The empirical study confirmed that this approach does not lead to

any systematic bias of the resulting index numbers. Despite that, a switch towards ratios of geometric mean prices was decided with the most recent CPI basket update, which took place in January 1995. This is because, in contrast with ratios of geometric mean prices, the ratios of arithmetic mean prices tend to give a higher influence on the estimate of price change to more expensive items, by the way of their implicit weighting. The danger could be reduced, or altogether eliminated, if averaging was done within commodity groups that are homogeneous from the point of view of price levels, or if sampling was random. Neither is the case in the Canadian CPI practice. The proposition of creating commodity groups homogeneous from the viewpoint of price levels (not price change!) is unworkable, while true random sampling of items whose prices are collected remains a very remote proposition, at best.

Another nicety of micro-indices calculated using geometric means is the possibility of their double interpretation. A ratio of equiweighted geometric mean prices is equal to an equiweighted geometric mean of price relatives. Both interpretations have some merit. A mean of price relatives corresponds to the idea of estimating price change, while ratio of mean prices conveys the idea of transitivity.

The Canadian approach to the micro-index problem is pragmatic, and based on statistical rather than economic considerations. There are other schools of thinking, though, that suggest the use of the same conceptual framework to define micro-indices as that used to define the macro-index structure of the CPI. One may quote here the Swedish approach, in which the estimation of micro-indices approximates the Edgeworth formula (Dalén [1992]), and the approach suggested by Balk [1991], to approximate the Laspeyres formula. Both these formulae belong to a family of basket-defined indices.

The idea of a consistent approach to the CPI construction at all aggregation levels is certainly interesting and appealing. Yet, the question remains whether enforcing the basket approach, or an akin concept, upon micro-indices is worth the effort and, indeed, desirable. Retail transactions, as identified at the lowest level of detail (that means not only with the variety and brand of the purchased item, but also with the name of the outlet, as well as with conditions and time of the purchase) resemble, by their volatility, the Brownian movements. If the analogy holds, they should be described by statistical observation, rather than by any preconceived model of behaviour. This is in contrast with broader categories of consumer goods and services, whose purchases exhibit certain constancy due to lasting macro-economic and macro-social forces, therefore justifying the concept of baskets. The discussion on micro-index formulae cannot be completed without taking into account other related topics, particularly the sample design. There is a relationship between the way items are sampled and the need of sample matching, which may influence the choice of micro-index formulae. Also the extent of stratification in the sampling procedure may affect the choice of these formulae. In fact, this is a two-way relationship. The choice of micro-index formulae, itself, may favour a more or less detailed stratification for the purpose of sampling of items. Prices Division recognises these relationships and intends to pursue discussions in a broader context when sample redesign will be on the table.

ANNEX I

**DIRECT AND CHAIN PRICE MICRO-INDICES
FOR SOFT DRINKS, WOMEN'S SHOES, AND MILK
IN THE PROVINCE OF ONTARIO,
FROM JANUARY 1989 TO JANUARY 1994**

Their formulae are shown in the Annex II

Similar data for other commodities are available on request.

Each table in Annex I relates to one commodity and contains:

- ❖ series of **direct micro-indices on various time bases**, calculated using the following six index formulae:
 - **RAMP** - ratios of equiweighted arithmetic mean prices,
 - **RGMP** - ratios of equiweighted geometric mean prices,
 - **RHMP** - ratios of equiweighted harmonic mean prices,
 - **AMPR** – equiweighted arithmetic means of price relatives,
 - **GMPR** – equiweighted geometric means of price relatives, and
 - **HMPR** – equiweighted harmonic means of price relatives,
as well as
- ❖ series of **chain micro-indices on the December 1988 time base**, obtained by linking these direct micro-indices.

Tables 1a and 2a contain series of direct **month-to-month indices** as well as series of chain indices obtained by their **monthly linking** (with links in every month from January 1989 to December 1993).

Tables 1b and 2b contain series of direct indices **on the last December time base** as well as series of chain indices obtained by their **yearly linking** (with links in every December, from 1989 to 1993).

Tables 1c and 2c contain series of direct indices **on the December 1988 time base** (up to December 1993) and direct indices on the December 1993 time base (for January 1994 only); as well as chain indices obtained by **quinquennial linking** (in fact only one link was used, in December 1993).

Direct micro-indices in **Tables 1a, 1b and 1c** were derived from **bilaterally matched samples of prices** (i.e. using prices from the intersection of outlets that provided price data in the base and the observation months of any given direct index).

Direct micro-indices in **Tables 2a, 2b and 2c** were derived from **common samples of prices** (i.e. using prices from the intersection of outlets that provided price data in the months from December 1988 to January 1994).

YEARLY LINKING OF DIRECT MICRO-INDICES ON THE PREVIOUS DECEMBER TIME BASE
CALCULATED USING PRICES FROM A COMMON SAMPLE

Commodity: Women's Shoes

Province: Ontario

Year	Direct indices on the previous December time base calculated as						Indices on the December 1988 time base obtained by linking every December the indices from the left-hand column

MONTHLY LINKING OF DIRECT MONTH-TO-MONTH MICRO-INDICES
CALCULATED USING PRICES FROM A COMMON SAMPLE

Commodity: Milk

Province: Ontario

Year	Direct month-to-month indices calculated as						Indices on the December 1988 time base obtained by linking every month the indices from the left-hand column

FORMULAE OF PRICE MICRO-INDICES

Formulae of direct indices	p.1
Formulae of chain indices	p. 2
Definition of the symbols used	p. 3

FORMULAE OF DIRECT MICRO-INDICES

FOR THE OBSERVATION MONTH t

on the base of the month b

$$P_{t/b}^{Dir.}$$

RAMP	$\frac{\left[\sum_{i=1}^N p_t^i \right] \div N}{\left[\sum_{i=1}^N p_b^i \right] \div N}$	AMPR	$\frac{\sum_{i=1}^N [p_t^i / p_b^i]}{N}$
RGMP	$\frac{\sqrt[N]{\prod_{i=1}^N p_t^i}}{\sqrt[N]{\prod_{i=1}^N p_b^i}}$	GMPR	$\sqrt[N]{\prod_{i=1}^N [p_t^i / p_b^i]}$
RHMP	$\frac{N \div \sum_{i=1}^N [1 / p_t^i]}{N \div \sum_{i=1}^N [1 / p_b^i]}$	HMPR	$\frac{N}{\sum_{i=1}^N [p_b^i / p_t^i]}$

RAMP Ratio of Arithmetic Mean Prices (equiweighted);

RGMP Ratio of Geometric Mean Prices (equiweighted);

RHMP Ratio of Harmonic Mean Prices (equiweighted);

AMPR Arithmetic Mean of Price Relatives (equiweighted);

GMPR Geometric Mean of Price Relatives (equiweighted);

HMPR Harmonic Mean of Price Relatives (equiweighted).

FORMULAE OF CHAIN MICRO-INDICES

FOR THE OBSERVATION MONTH t IN YEAR x

on the December 1988 time base

$$P_{t\{x\}/D\{88\}}^{Chain}$$

Monthly linking <p>Chain indices obtained by linking direct month-to-month micro-indices to each other every month</p>	$\prod_{m\{y\}=J\{89\}}^{t\{x\}} P_{m\{y\}/(m-1)\{y\}}^{Dir.}$
Annual linking <p>Chain indices obtained by linking direct micro-indices on the previous December time base to each other every December</p>	$P_{t\{x\}/D\{x-1\}}^{Dir.} * \prod_{D\{y\}=D\{88\}}^{D\{x-1\}} P_{D\{y\}/D\{y-1\}}^{Dir.}$
Quinquennial linking <p>(only one index)</p> <p>Chain index obtained by linking the January 1994 direct micro-index on the December 1993 time base to the direct micro-index for December 1993 on the 1988 time base</p>	$P_{J\{94\}/D\{93\}}^{Dir.} * P_{D\{93\}/D\{88\}}^{Dir.}$

DEFINITIONS OF THE SYMBOLS USED

p_t^i

i - th price quote collected in the observation time t ;

p_b^i

i - th price quote collected in the base time b ;

$p_{m\{y\}}^i$

i - th price quote collected in the month m of the year y ;

$p_{m\{y-1\}}^i$

i - th price quote collected in the month m

of the year preceding the year y ;

$P_{t/b}^{Dir.}$

direct micro-index comparing prices in the observation time t
to those in the base time b ;

$P_{m\{y\}/(m-1)\{y\}}^{Dir.}$

direct month-to-month price micro-index;

$P_{D\{y\}/D\{y-1\}}^{Dir.}$

direct December-to-December price micro-index;

$P_{t\{x\}/D\{88\}}^{Chain}$

chain price index comparing prices in the observation month t
of the year x to those in December 1988 ;

N

total number of price quotes used in the calculation of a given micro-index. In the case of **bilaterally matched samples**, it is equal to the number of price quotes from the intersection of outlets that provided data in both the base and the observation months of the given direct index. For a month-to-month direct index, this number is as follows:

$$N = n_{(m-1)\{y\}} \cap n_{m\{y\}} .$$

In the case of a **common price sample**, it is equal to the number of price quotes from the intersection of outlets that provided data in all the months from December 1988 to January 1994, as follows:

$$N = \bigcap_{m=D\{88\}}^{J\{94\}} n_m , \text{ where:}$$

n_m is the number of price quotes in the price sample originally selected in any month m , while

$n_{m\{y\}}$ and $n_{(m-1)\{y\}}$ are the numbers of price quotes in the price samples originally selected in the two consecutive months m and $(m-1)$ of the year y .

ANNEX III

Examples of actual monthly price quotes for soft drinks collected in chosen Toronto outlets in 1989

Outlets	Year, months											
	89 01	89 02	89 03	89 04	89 05	89 06	89 07	89 08	89 09	89 10	89 11	89 12
